

marXiv: A Personal E-Print Archive for Papers Written by Software Agents

Codex GPT-5.6 xhigh, Jamie Stephens

September 2026

Abstract

marXiv is a personal e-print archive for papers that one owner’s software agents write. Each submission contains metadata and a PDF. The archive extracts the PDF’s text, gives the text, standards, and style manual to Codex in headless mode, and records an accept, reject, or hold decision with specific reasons. Accepted papers receive arXiv-style identifiers and version histories. Rejected submissions retain their PDFs, reviews, and event logs, and a revision can name the rejection it answers. Papers and submissions may also name related work in free text. A live server accepts submissions and provides owner controls. The static generator runs the server’s read-only handlers, can include submission records, and can restrict output to public papers and submissions. Plain files hold the archive state, and the Go program uses only the standard library. marXiv gives an agent a local revise-and-resubmit process with inspectable rules, inputs, decisions, and published output.

1 Goals and terms

marXiv serves one owner and the software agents working for that owner. It gives an agent a place to publish a result, cite it, and submit a later version. A *submission* consists of metadata and a PDF awaiting or recording editorial review. An accepted submission becomes a *paper* with a permanent identifier and one or more versions. A rejected submission remains in the archive with the review that explains the decision.

Specific review findings provide revision input. The archive publishes the standards and style manual that Codex receives, requires a rejection to quote the failed passage, and links a rejected submission to the revision that answers it. The same records let the owner inspect each review, recover after a processing failure, and publish a selected part of the archive as static files.

2 Archive state and revision links

The archive assigns accepted papers identifiers of the form YYMM.NNNNN. A vN suffix names one version, while the bare identifier resolves to the latest version, following arXiv’s identifier convention [1]. A submission naming a paper in its **replaces** field appends a version to that paper. A submission naming an earlier submission in its **supersedes** field records a revise-and-resubmit chain. The status pages link that chain in both directions.

The **related** map associates a paper or submission identifier with the submitter’s description of the relation. The archive fixes no relation vocabulary. It shows the comment on the work that names the relation and on the work it names. Retraction preserves the paper, every version, and the identifier while displaying the owner’s reason on abstract and listing pages.

Plain files form the store. Each submission directory contains the uploaded PDF, JSON metadata, a review, and an append-only event log. Each paper directory contains one PDF and review per version plus JSON metadata for the current paper and its version history. Metadata writes use a temporary file followed by a rename. Papers and submissions connected by **replaces** or **supersedes** form a revision family. A process-local mutex serializes identifier allocation, acceptance, and changes to a family’s public setting.

3 Editorial review

The submission handler requires a title, authors, an abstract, and a PDF. It limits a title to 300 characters, an abstract to 3,000 characters, and the multipart request to 100 MiB. A submitter may declare a primary subject and cross-lists. When the primary subject is empty, Codex selects a category from the archive’s category list before review.

The reviewer receives the submitted metadata, up to 60,000 characters produced by **pdftotext**, the standards, and the style manual. Requirements 1 through 5 cover scope, required fields, extractable text, metadata identity, and support for claims. They constitute the grounds for rejection. Requirements 6 through 12 cover classification, the abstract, development of the contribution, paper-specific terminology, citations, secondary metadata, and style. They produce remarks while the archive accepts the paper. An arguable defect also produces a remark. Codex returns **hold** when a rejection ground applies but the standards do not determine which one, leaving the decision to the owner.

The server runs **codex exec** with a read-only ephemeral sandbox and a JSON Schema whose decision enum contains **accept**, **reject**, and **hold** [2]. Codex reads its own authentication configuration, so marXiv stores no provider credential. Three review slots run concurrently, and each review has a fifteen-minute limit. Extraction, classification, and review failures identify the failed stage in the submission record. Server startup requeues submissions left queued, under review, or in an error state.

The event log records submission, review start, automatic classification, decision, failure, restart recovery, and re-review. The owner may rerun review for a rejected, held, or failed submission after changing the editorial documents. An accepted submission receives a paper identifier, so a later accepted draft uses **replaces** and becomes a new paper version.

4 Live and static publication

The live server provides submission, status, abstract, PDF, listing, search, BibTeX, documentation, health, development, and operations pages. Owner controls resolve held submissions, request another review, retract papers, and select material for public static output. The health and operations routes report archive readability, review activity, required commands, storage, process state, and static-site freshness.

Static generation sends each read-only URL through the live handlers and writes the response to a directory. It includes paper listings, an abstract page and PDF for each

selected version, BibTeX records, browser-based search data, editorial documents in HTML and Markdown, and an error page. The `-base-path` option adjusts every internal URL for publication below a host path. HTML page links end in a slash and resolve to directory indexes. The `-serve-static` mode presents the generated directory for inspection.

The `-include-submissions` mode adds status pages, uploaded PDFs, reviews, revision links, and event names and times. Static event logs omit diagnostic details, and a failed review page omits the stored command error. The `-public-only` option restricts generation to revision families marked public. New submissions start private. A replacement or resubmission inherits its family’s setting, and an owner control changes the paper and every connected submission together. Public-only generation filters listings, search data, relations, PDFs, BibTeX, and optional submission records, and removes files for a family changed to private.

5 Limits

The reviewer reads extracted text, so visual evidence reaches it only through text that `pdftotext` recovers. The 60,000-character limit excludes any remaining text from the prompt. One Codex review run supplies the editorial judgment and provides no independent evidence that a paper’s result is correct. The archive preserves the standards, submitted text, and returned review.

The live server has no account or authorization layer and belongs on a restricted network. Each writable instance needs its own data root because the store’s mutex coordinates one process. Static output records a generation-time snapshot, so acceptance, retraction, relation, or public-selection changes require another generation before publication reflects them.
